### Supplementary Figure 1 | Illustration of fNIRS Optode Position.

We used two identical  $3 \times 2$  optode probe sets, with each probe set (inter-optode distance of 30 mm) consisting of 3 light emitters (red) and 3 detectors (blue), and 7 channels. Each probe set was separately placed on the right temporo-parietal junction (rTPJ) or the right dorsolateral prefrontal cortex (rDLPFC) according to the relevant standard positions of P6 and F4 in the international 10-10 system for electroencephalogram electrode placement<sup>1-4</sup>.

### Supplementary Figure 2 | GNS and group-averaged activity based on the deoxygenated hemoglobin (Deoxy-Hb) signal.

We similarly applied the wavelet-based global noise removal technique to Deoxy-Hb time series and performed Wavelet Transform Coherence analysis to calculate the GNS of Deoxy-Hb signal for each three-person group. **a**, The F-map of the Bonding × Role interaction on GNS. We found a similar Bonding × Role interaction effect at channels 3 and 9 of rTPJ (channel 3:  $F_{1,84} = 6.777$ ,  $p = 0.011$ ,  $\eta^2 = 0.075$ ; channel 9:  $F_{1,84} = 6.999$ ,  $p = 9.73 \times 10^{-3}$ ,  $\eta^2 = 0.077$ ) but did not survive from FDR-correction for 14 channels. **b**, Regarding the GNS for channels 8, 11, 4, and 13, although the pattern at channel 8 was similar to that observed in Oxy-Hb analysis, there were no significant Bonding × Role interaction ( $F_{1,84} = 0.006$ ,  $p = 0.938$ ,  $\eta^2 = 7.14 \times 10^{-5}$ ). Mixed-model ANOVAs,  $n = 86$  three-versus-three-person intergroup contest sessions. Data are plotted as boxplots for each condition in which horizontal lines indicate median values, boxes indicate 25/75% quartiles, and whiskers indicate the 2.5-97.5% percentile range. Data points outside the range are shown separately as circles. Solid lines start from the mean and reflect the intervals for the Mean  $\pm$  S.E. \*  $p < 0.05$ , \*\*  $p < 0.01$ . *n.s.* not significant.

### Supplementary Figure 3 | Gender Effect.

All sessions were classified as all-male sessions ( $n = 38$  six-person sessions) and all-female sessions ( $n = 48$  six-person sessions). To examine whether session gender influenced the neural response (including GNS, within-group averaged neural activity and group-averaged functional connectivity), we included Session gender (all-male vs. all-female sessions) as a between-session factor. **a**, Session gender produced a main effect showing stronger GNS in the rDLPFC ( $p_s < 0.05$ , FDR correction, channel 6:  $F_{1, 82} = 11.085$ ,  $p = 1.31 \times 10^{-3}$ ,  $\eta^2 = 0.119$ ; channel 8:  $F_{1, 82} = 8.698$ ,  $p = 0.004$ ,  $\eta^2 = 0.096$ ) and rTPJ (channel 13:  $F_{1, 82} = 7.142$ ,  $p = 0.009$ ,  $\eta^2 = 0.080$ ) in all-female sessions than all-male sessions, but Session gender did not interact with Bonding or Role ( $p_s > 0.05$ , Supplementary Table 10a provides the full statistical report of each channel). **b**, **c**, There was no effect of Session gender on within-group averaged neural activity ( $F_{1, 82} = 2.815$ ,  $p = 0.097$ ,  $\eta^2 = 0.033$ ) nor group-averaged functional connectivity ( $F_{1, 82} = 1.169$ ,  $p = 0.283$ ,  $\eta^2 = 0.014$ , Supplementary Table 10c provides the full statistical report of each channel pair). Mixed-model ANOVAs on 86 three-versus-three-person intergroup contest sessions. Data are plotted as boxplots for each condition in which horizontal lines indicate median values, boxes indicate 25/75% quartiles, and whiskers indicate the 2.5-97.5% percentile range. Data points outside the range are shown separately as circles. Solid lines start from the mean and reflect the intervals for the Mean  $\pm$  S.E. \*\*  $p < 0.01$ , *n.s.* not significant.

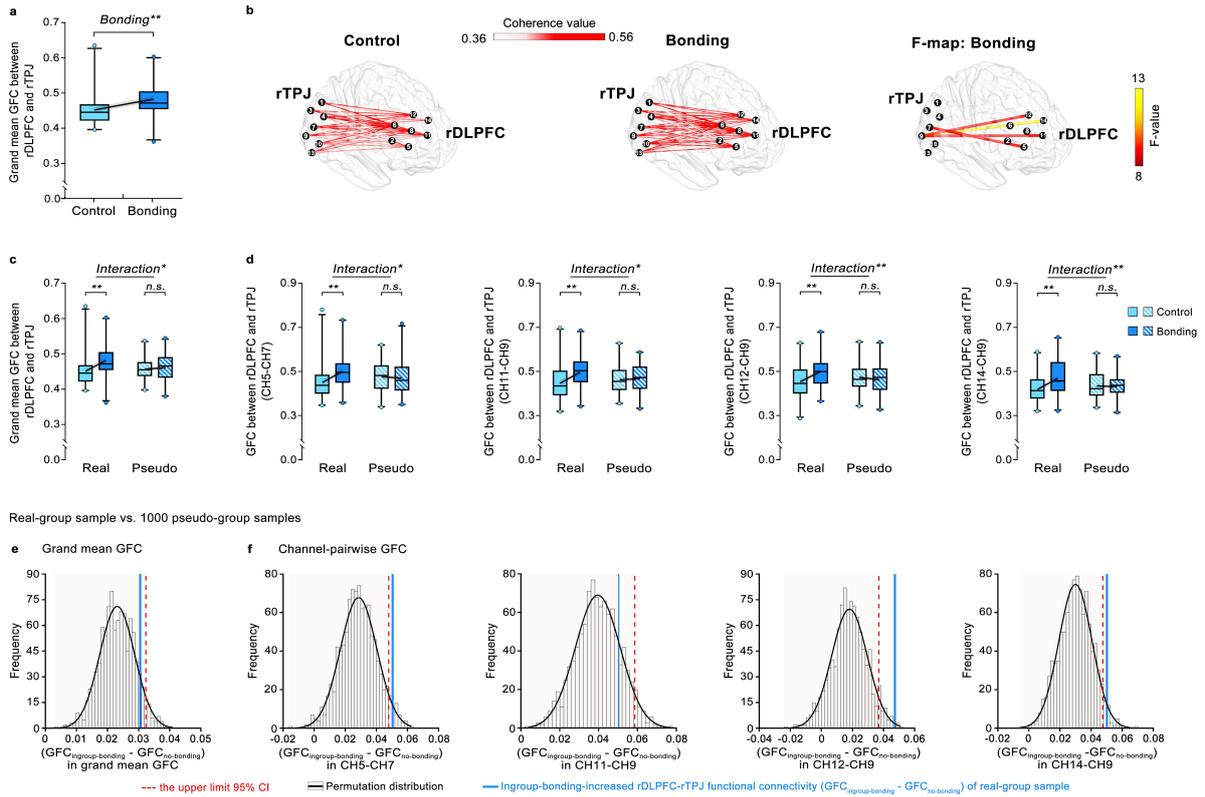

### Supplementary Figure 4 | Stronger Bonding effect on group-level rDLPFC activity in real than pseudo groups.

**a**, We conducted Role (attacker vs. defender)  $\times$  Bonding (in-group bonding vs. no-bonding control)  $\times$  Group (real vs. pseudo groups) ANOVA on the group-level neural activity (GNA) in rDLPFC (i.e. channel 8), 86 six-person real groups and 86 six-person pseudo groups. We found significant interactions of Bonding and Group when comparing real groups with pseudo groups ( $F_{1,168} = 4.053$ ,  $p = 0.046$ ,  $\eta^2 = 0.024$ ). The reduced rDLPFC activity following in-group bonding (vs. non-bonding control) was only observed in the real group ( $F_{1,84} = 4.034$ ,  $p = 0.048$ ,  $\eta^2 = 0.046$ ), but not the pseudo group ( $F_{1,84} = 1.108$ ,  $p = 0.296$ ,  $\eta^2 = 0.013$ ). Mixed-model ANOVAs, 86 six-person groups, respectively for real and pseudo groups. Data are plotted as boxplots for each condition in which horizontal lines indicate median values, boxes indicate 25/75% quartiles, and whiskers indicate the 2.5-97.5% percentile range. Data points outside the range are shown separately as circles. Solid lines start from the mean and reflect the intervals for the Mean  $\pm$  S.E. \*  $p < 0.05$ , *n.s.* not significant. **b**, One-sided permutation test was used to verify the stronger Bonding effect on group-level rDLPFC activity in real than pseudo groups. We compared the real-group sample with 1000 pseudo-group samples<sup>1-4</sup>. We tested the ingroup-bonding-decreased group-level neural activity in the rDLPFC ( $GNA_{\text{ingroup-bonding}} - GNA_{\text{no-bonding}}$ ) of the real-group sample against permutation samples based on the mean differences of rDLPFC activity between in-group bonding and no-bonding control ( $n = 1000$ , each permutation sample contains 172 within-condition three-person pseudo groups). We showed that the observed ingroup-bonding-decreased group-level rDLPFC activity in the real groups was outside the lower limit of 95% *CI* of the permutation distribution.

## Supplementary Figure 5 | Stronger Bonding effect on group-level rDLPFC-rTPJ connectivity in real than pseudo groups.

**a, b**, We conducted Bonding (in-group bonding vs. no-bonding control)  $\times$  Role (attacker vs. defender) ANOVAs ( $n = 86$  three-versus-three-person intergroup contest sessions) on the grand-mean rDLPFC-rTPJ functional connectivity (**a**) and channel-pairwise rDLPFC-rTPJ functional connectivity in the real groups (**b**). We found that the increased group-level functional connectivity (GFC) following in-group bonding (vs. non-bonding control) in both grand mean rDLPFC-rTPJ connectivity (**a**,  $F_{1,84} = 9.047$ ,  $p = 0.003$ ,  $\eta^2 = 0.097$ ), and channel-pairwise rDLPFC-rTPJ connectivity (**b**, CH5-CH7:  $F_{1,84} = 9.126$ ,  $p = 0.003$ ,  $\eta^2 = 0.098$ ; CH11-CH9:  $F_{1,84} = 8.952$ ,  $p = 0.004$ ,  $\eta^2 = 0.096$ ; CH12-CH9:  $F_{1,84} = 8.783$ ,  $p = 0.004$ ,  $\eta^2 = 0.095$ ; CH14-CH9:  $F_{1,84} = 11.320$ ,  $p = 1.16 \times 10^{-3}$ ,  $\eta^2 = 0.119$ ; survived from FDR correction for 49 channel-pairs).

**c, d**, We conducted Bonding (in-group bonding vs. no-bonding control)  $\times$  Role (attacker vs. defender)  $\times$  Group (real vs. pseudo groups) ANOVAs on the group-level rDLPFC-rTPJ functional connectivity (86 six-person real groups and 86 six-person pseudo groups). We found significant interactions of Bonding and Group when comparing real groups with pseudo groups (**c**, grand mean level:  $F_{1,168} = 4.406$ ,  $p = 0.037$ ,  $\eta^2 = 0.026$ ; **d**, channel-pairwise level: CH5-CH7:  $F_{1,168} = 5.871$ ,  $p = 0.016$ ,  $\eta^2 = 0.034$ ; CH11-CH9:  $F_{1,168} = 4.429$ ,  $p = 0.037$ ,  $\eta^2 = 0.026$ ; CH12-CH9:  $F_{1,168} = 6.892$ ,  $p = 0.009$ ,  $\eta^2 = 0.039$ ; CH14-CH9:  $F_{1,168} = 7.398$ ,  $p = 0.007$ ,  $\eta^2 = 0.042$ ; survived FDR correction for the 4 testing channel-pairs). The increased rDLPFC-rTPJ functional connectivity following in-group bonding (vs. non-bonding control) was only observed in real groups (**a-d**), but not pseudo groups (**c**, grand mean level:  $F_{1,84} = 0.224$ ,  $p = 0.638$ ,  $\eta^2 = 0.003$ ; **d**,

channel-pairwise level: CH5-CH7:  $F_{1,84} = 0.169$ ,  $p = 0.682$ ,  $\eta^2 = 0.002$ ; CH11-CH9:  $F_{1,84} = 0.094$ ,  $p = 0.759$ ,  $\eta^2 = 0.001$ ; CH12-CH9:  $F_{1,84} = 0.534$ ,  $p = 0.467$ ,  $\eta^2 = 0.006$ ; CH14-CH9:  $F_{1,84} = 0.088$ ,  $p = 0.767$ ,  $\eta^2 = 0.001$ ). Mixed-model ANOVAs, 86 three-versus-three-person intergroup contest sessions for pseudo groups. Data are plotted as boxplots for each condition in which horizontal lines indicate median values, boxes indicate 25/75% quartiles, and whiskers indicate the 2.5–97.5% percentile range. Data points outside the range are shown separately as circles. Solid lines start from the mean and reflect the intervals of Mean  $\pm$  S.E. \*  $p < 0.05$ , \*\*  $p < 0.01$ . **e, f**, We compared the Bonding effect on rDLPFC-rTPJ connectivity between real and pseudo groups using one-sided permutation test. Specifically, for both grand mean GFC and channel-pairwise GFC, we compared the real-group sample with 1000 pseudo-group samples<sup>1-4</sup>. We tested the ingroup-bonding-increased rDLPFC-rTPJ functional connectivity ( $GFC_{\text{ingroup-bonding}} - GFC_{\text{no-bonding}}$ ) of the real-group sample against permutation samples based on the mean differences of GFC between in-group bonding and no-bonding control in pseudo-group samples ( $n = 1000$ , each permutation sample contains 172 within-condition three-person pseudo groups). We showed that the observed ingroup-bonding-increased rDLPFC-rTPJ connectivity in real groups were outside the upper limit of 95% CI of the permutation distribution (at channel-pairs: CH5 - CH7; CH12 - CH9:  $p = 0.005$ ; and CH14 - CH9).

Preference for social hierarchy	3.31 (0.06)	3.39 (0.07)	3.47 (0.07)	3.32 (0.07)	0.55	0.62	0.09
Intergroup discrimination (iDG0)	6.07 (0.59)	6.55 (0.61)	7.26 (0.79)	7.05 (0.61)	0.20	0.83	0.60

1 Note: We conducted 2 (Bonding: in-group bonding vs. no-bonding control) × 2 (Role: attacker  
2 vs. defender) mixed-model ANOVAs ( $n = 91$  three-versus-three-person intergroup contest  
3 sessions for **a** and  $n = 86$  three-versus-three-person contest sessions for **b**) on the demographic  
4 information and social-related traits. Empathic capacity was measured using the Interpersonal  
5 Reactivity Index<sup>1</sup>, which consists of 28 items on a 5-point (0-4) Likert scale (higher scores  
6 reflecting more empathic of an individual). Cooperative personality was measured by the  
7 cooperative subscale of the Cooperation and Competition Personality scale<sup>2</sup> (13 items on a  
8 5-point (1-5) Likert scale). Social value orientation was measured by the 6 primary items of the  
9 Social Value Orientation Slider task<sup>3</sup>. Prosocial personality was measured by the Social  
10 Responsibility, Other-Oriented Moral Reasoning, and Mutual Concerns Moral Reasoning  
11 subscales of Prosocial Personality Battery<sup>4</sup>, which consists of 13 items on a 5-point (1-5) Likert  
12 scale (higher values reflecting more prosocial of an individual). Impulsiveness was measured  
13 using BAS subscale of the Behavioral Inhibition/Behavioral Activation Scales, BIS/BAS<sup>5</sup>, which  
14 consists of 13 items on 4-point (1-4) Likert scale (higher values reflecting more appetitive  
15 motives). Justice sensitivity was measured using Justice Sensitivity Inventory<sup>6</sup>, which consists of  
16 40 items on 6-point (0-5) Likert scale (higher values reflecting more sensitive to justice).  
17 Individual's preference for social hierarchy was measured using Social Dominance Orientation  
18 (SDO) scale<sup>7</sup>, which consists of 16 items on 7-point (1-7) Likert scale (higher values reflecting  
19 stronger preference for inequality among social groups). The individual's baseline intergroup  
20 discrimination was indexed by the intergroup bias in the intergroup Dictator Game (iDG0: split  
21 20 monetary units between in-group and out-group members).

41 **Supplementary Table 2 | Payoff matrix of one-round intergroup contest game.**

Group	Role	Initial endowment (MU)	Individual contribution ( $x_i / y_i$ )	Group's pool C ( $0 \leq C \leq 60$ )	Payoff	
					Attackers lose $C_A \leq C_D$	Attackers win $C_A > C_D$
Attacker group	Attacker <sub>1</sub>	20	$x_1$	$C_A = (x_1 + x_2 + x_3)$	$20 - x_1$	$20 - x_1 + (60 - C_D)/3$
	Attacker <sub>2</sub>	20	$x_2$		$20 - x_2$	$20 - x_2 + (60 - C_D)/3$
	Attacker <sub>3</sub>	20	$x_3$		$20 - x_3$	$20 - x_3 + (60 - C_D)/3$
Defender group	Defender <sub>1</sub>	20	$y_1$	$C_D = (y_1 + y_2 + y_3)$	$20 - y_1$	0
	Defender <sub>2</sub>	20	$y_2$		$20 - y_2$	0
	Defender <sub>3</sub>	20	$y_3$		$20 - y_3$	0

42 Note: For each intergroup contest round, each individual received an initial endowment of 20 Monetary Units (MUs). Members of  
 43 attacker (defender) group could each contribute  $x$  ( $y$ ) out of 20 MUs. Each individual decided the amount ( $x_i$  for attacker group, and  $y_i$   
 44 for defender group,  $0 \leq x_i \leq 20$ ,  $0 \leq y_i \leq 20$ ) to the group's pool C ( $0 \leq C \leq 60$ ,  $C_A = [x_1 + x_2 + x_3]$ ,  $C_D = [y_1 + y_2 + y_3]$ ). When  $C_A \leq C_D$ ,  
 45 defender group would survive attacker group's attack and the members of both groups would earn what remained from their  
 46 endowment (i.e.,  $20 - \{x, y\}$ ). When  $C_A > C_D$ , defender group failed and left with 0. Attacker group won and took away defender  
 47 group's remaining MU ( $60 - C_D$ ), which were divided equally among members of attacker group (each member:  $[(60 - C_D)/3]$ ) and  
 48 added to their remaining endowments ( $20 - x_i$ ).

49 **Supplementary Table 3 | Full statistical reports for behavioral indices in the intergroup**  
 50 **contest game.**

51 **a, Descriptive statistics in each condition ( $n = 91$  intergroup contest sessions)**

Behavioral indices		No-bonding control ( $n = 44$ )		Ingroup-bonding ( $n = 47$ )

53

54 Note: Contribution was calculated by the averaging contributions within 3-person group and  
55 across 24 rounds (range: 0-20 monetary units). Within-group decision coordination was calculated  
56 by correlating the 24-round contributions of each pair of two participants within each 3-person  
57 group (resulting in 3 correlations per group) and averaging the 3 Fisher z-transformed correlation  
58 coefficients. Higher value indicates higher coordination in round-level contributions among the  
59 group members. The intergroup discrimination in the intergroup Dictator Game (iDG) was  
60 calculated by subtracting donations to out-group members from those to in-group members.  
61 Higher value indicates stronger intergroup discrimination. The intergroup discrimination in the  
62 likability rating was calculated by subtracting likability rating of out-group members from those to  
63 in-group members. Higher value indicates stronger intergroup discrimination. Mixed-model  
64 ANOVAs,  $n = 91$  three-versus-three-person intergroup contest sessions. Effects and p-values in  
65 bold indicate significant effects, \*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ .

13	62	-62	-10	13.65	BA37	Inferior Temporal Gyrus

67  
68 Note: To further confirm the anatomical position of the optode probe sets, the high-resolution  
69 T1-weighted structural images from 6 participants (4 males, Mean  $\pm$  SD = 22.5  $\pm$  2.26 years) were  
70 acquired using a 3-T Siemens Trio scanner at the MRI Research Centre, Beijing Normal  
71 University. For each participant, we normalized the structural image in SPM8 and then obtained  
72 the MNI coordinates of 14 channels through NIRS-SPM toolbox. Across participants, we  
73 calculated the mean MNI coordinates and standard deviation for each channel<sup>1</sup>. The anatomical  
74 coordinates of each optode were shown in the Table and further confirmed the anatomical  
75 localization of right rTPJ and rDLPFC.

160

161 Note: We first averaged the denoised Oxy-Hb neural activity in each channel across 3 participants  
162 of each real or pseudo group. We then performed coherence analyses between each of the 7  
163 channels in the rDLPFC with each of the 7 channels in the rTPJ (i.e., 49 channel pairs) to index  
164 channel-pairwise group-level functional connectivity (GFC) of rDLPFC–rTPJ and submitted the  
165 channel-pairwise GFC to Role-by-Bonding ANOVAs. Mixed-model ANOVAs,  $n = 86$   
166 three-versus-three-person intergroup contest sessions; \*  $p < 0.05$ , \*\*  $p < 0.01$ ; FDR-corrected  $p$ :  
167  $p$ -value corrected for the main effect of Bonding in all 49 channel pairs. Channel pairs and  
168  $p$ -values in bold indicate effects survived FDR correction.

169
